Feature selection versus feature extraction

Concept of filters vs wrappers

Concept of filters vs wrappers

mRMR

- **mRMR (minimum Redundancy Maximum Relevance)** is a feature-selection method that selects features that are **highly relevant to the target variable while being minimally redundant with each other.**
- Typically, relevance is measured using **mutual information** between each feature and the target, while redundancy is measured by mutual information between selected features. Features are added iteratively to maximize relevance and minimize redundancy.
- Implementation in Python
